Background

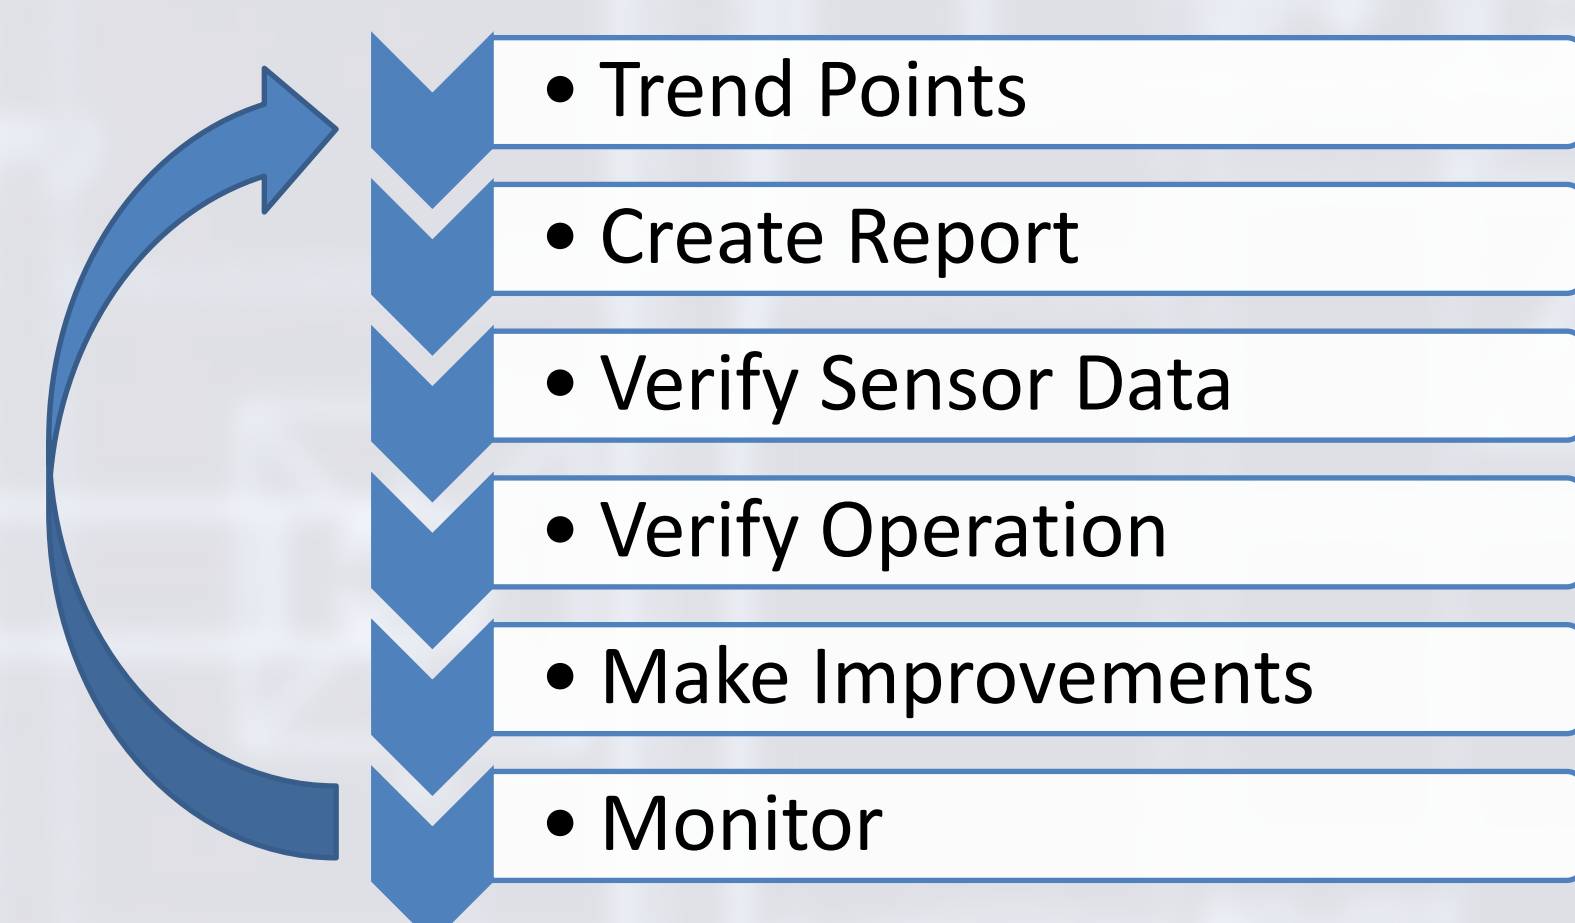

Over the last few years, the Cooper Union campus has not been as energy efficient as in the past. It is expected for a building's efficiency to decrease over time, and at a certain point it should be returned.

Problem Statement

Develop tools for building retuning which can facilitate the monitoring and verification of building data, increase energy efficiency, and reduce operational cost.

Building Retuning

Retuning is the monitoring and verification of a building's performance. The process tries to solve energy issues by modifying building operation at low or zero cost.

An Iterative Retuning Process

- ❖ Trend sensor data from the building management system
- ❖ Generate a report which makes the data readable
- ❖ Identify abnormal/outlier sensor data and investigate for faulty sensors; e.g., negative humidity data
- ❖ Identify abnormal/outlier equipment data and investigate for malfunctioning equipment; e.g., a jammed damper
- ❖ Make changes to the system
- ❖ Observe effects from changes by trending sensor data from BMS; start the process over

Motivation

- ❖ Potential to reduce utility costs by \$300K+ annually, which is approximately 2 full tuition scholarships.
- ❖ Reduce annual CO2e emissions by 1000 Mtons, which is equivalent to removing approx. 200 cars from the road¹.
- ❖ Support our building staff by helping them troubleshoot building faults.

Case Study 1: Air Handler Units (AHUs)

Air handlers are responsible for delivering breathable air of desirable quality to all rooms, and evacuating harmful contaminants from labs. Requires energy for heating/cooling coils and fans. Using a weekly data output from the BMS, a MATLAB script outputs an AHU report.

Example – AHU Tuning

Set Point [Blue bar]
Room Temp [Red bar]
 At night the room temp. should be set-back to reduce required cooling; solid red shows potential energy savings.

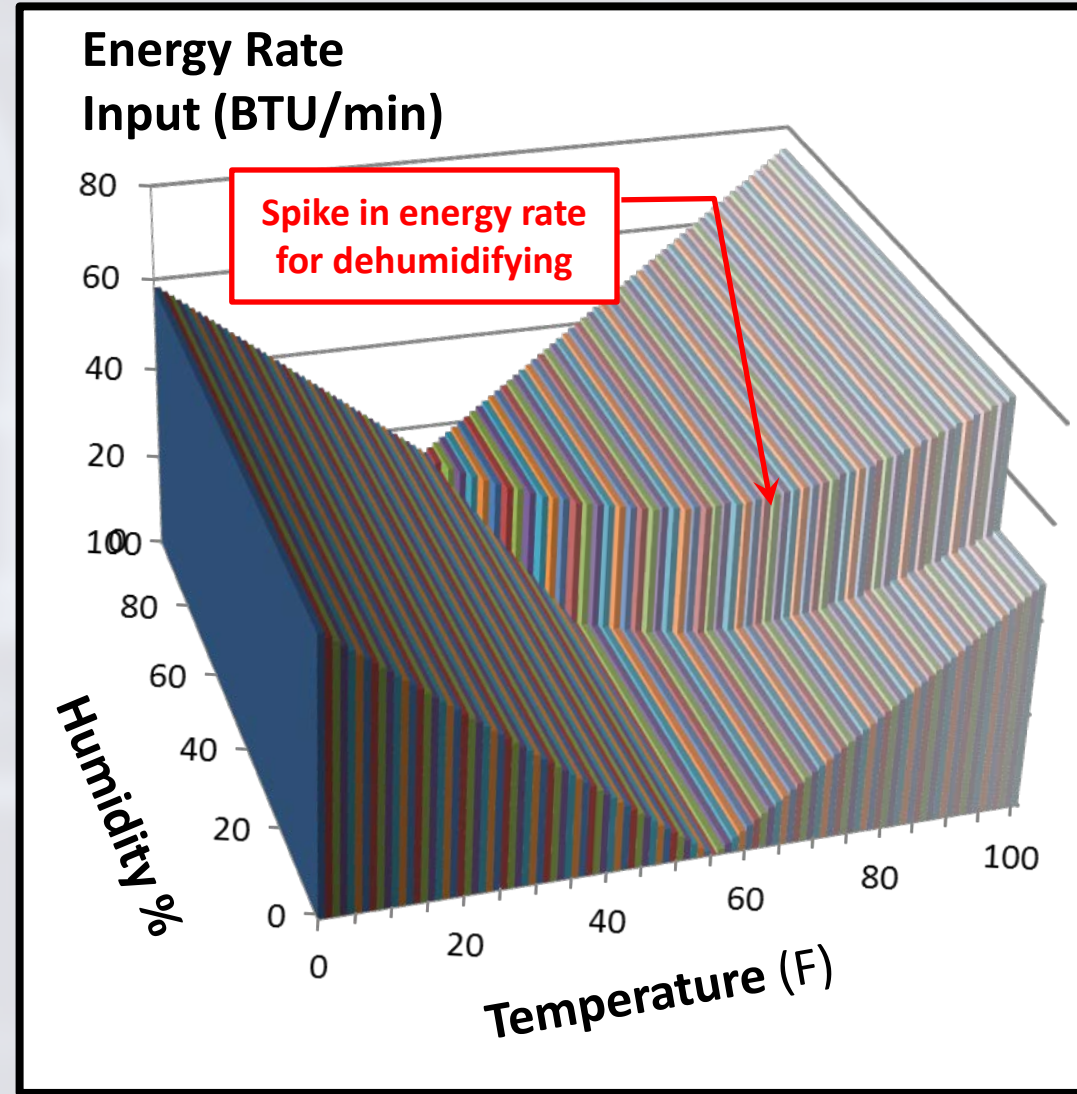

Example - Report

- Discharge Air Temperature Setbacks Enabled
 Potential Energy Savings: \$153/week
 WARNING: Discharge Air Temperature Unable to Meet Setpoint!
 WARNING: Discharge Air Temperature < 50F
 Potential Energy Savings: \$35 per week
 WARNING: Discharge Air Temperature Fluctuates!
 WARNING: Simultaneous Heating and Cooling!
 Potential Energy Savings: \$127 per week
- WARNING: No Static Pressure Setbacks!
 Potential Energy Savings: \$499 per week
 WARNING: Static Pressure is TOO HIGH!
 Dampers at maximum:
 x41CS_701_SAV_701_SUP_DMP_CMD
 x41CS_702_VAV_710_SUP_DMP_CMD
 x41CS_704_SAV_704_SUP_DMP_CMD
 x41CS_707_SAV_708_SUP_DMP_CMD
 x41CS_709_SAV_725_SUP_DMP_CMD
 x41CS_806_VAV_805_DMPR_CMD
 x41CS_807B_VAV_805A_DMPR_CMD
 x41CS_909_VAV_909_DMPR_CMD

Potential Savings ●
Potential Faults ●
 Weekly report gives textual fault callouts for operator and quantifies potential savings.

Enthalpy vs Temperature Control (Future Work)

Some modern buildings control air quality using enthalpy based control. Using the AHU analysis tool, enthalpy and temperature control can be compared directly in terms of energy usage. With more building data this can become a future study. The graph on the right shows how temperature and humidity can be converted to energy usage.

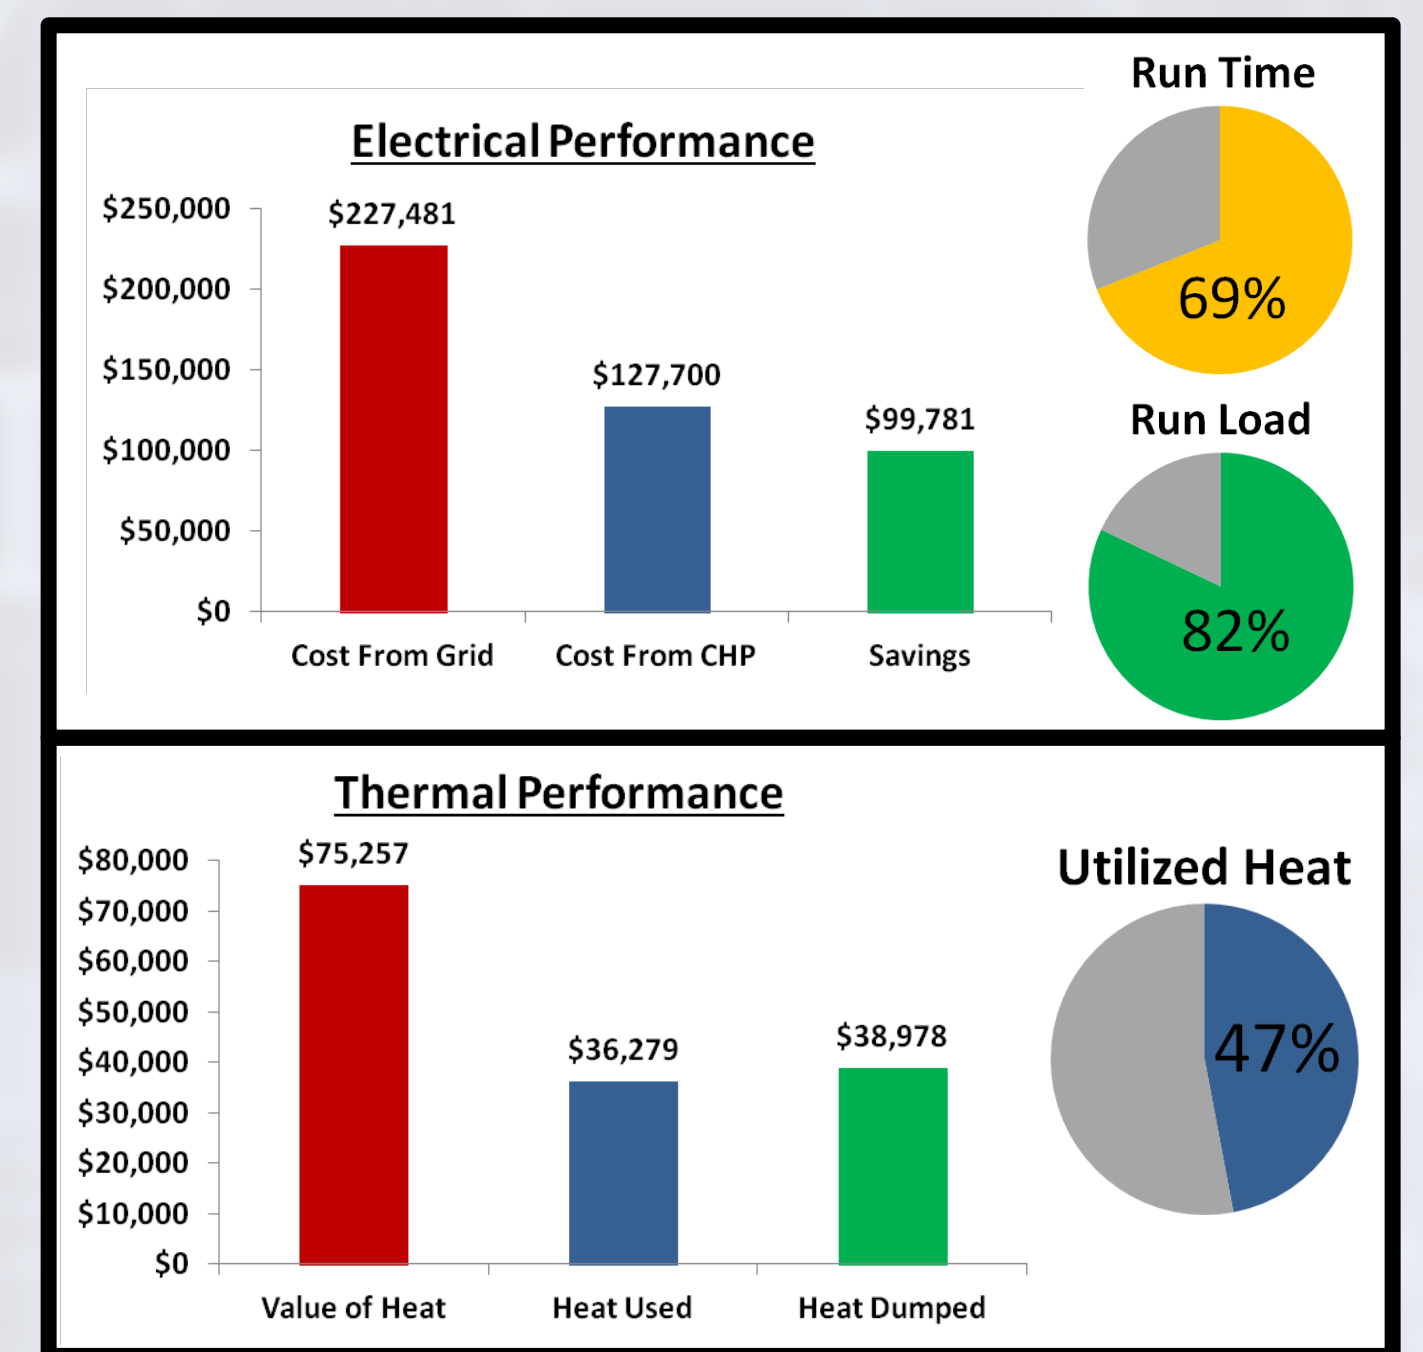

Energy rate to condition air at given temp. and humidity to discharge air set-point of 55°F and 60% RH.

Case Study 2: 41 CS Cogeneration (CHP) Report

Cogeneration, or Combined Heat and Power (CHP), is the process of generating electricity locally and using the 'waste' heat for the building's heating needs. Requires natural gas. Excel templates/reports created from BMS/Elite Energy data.

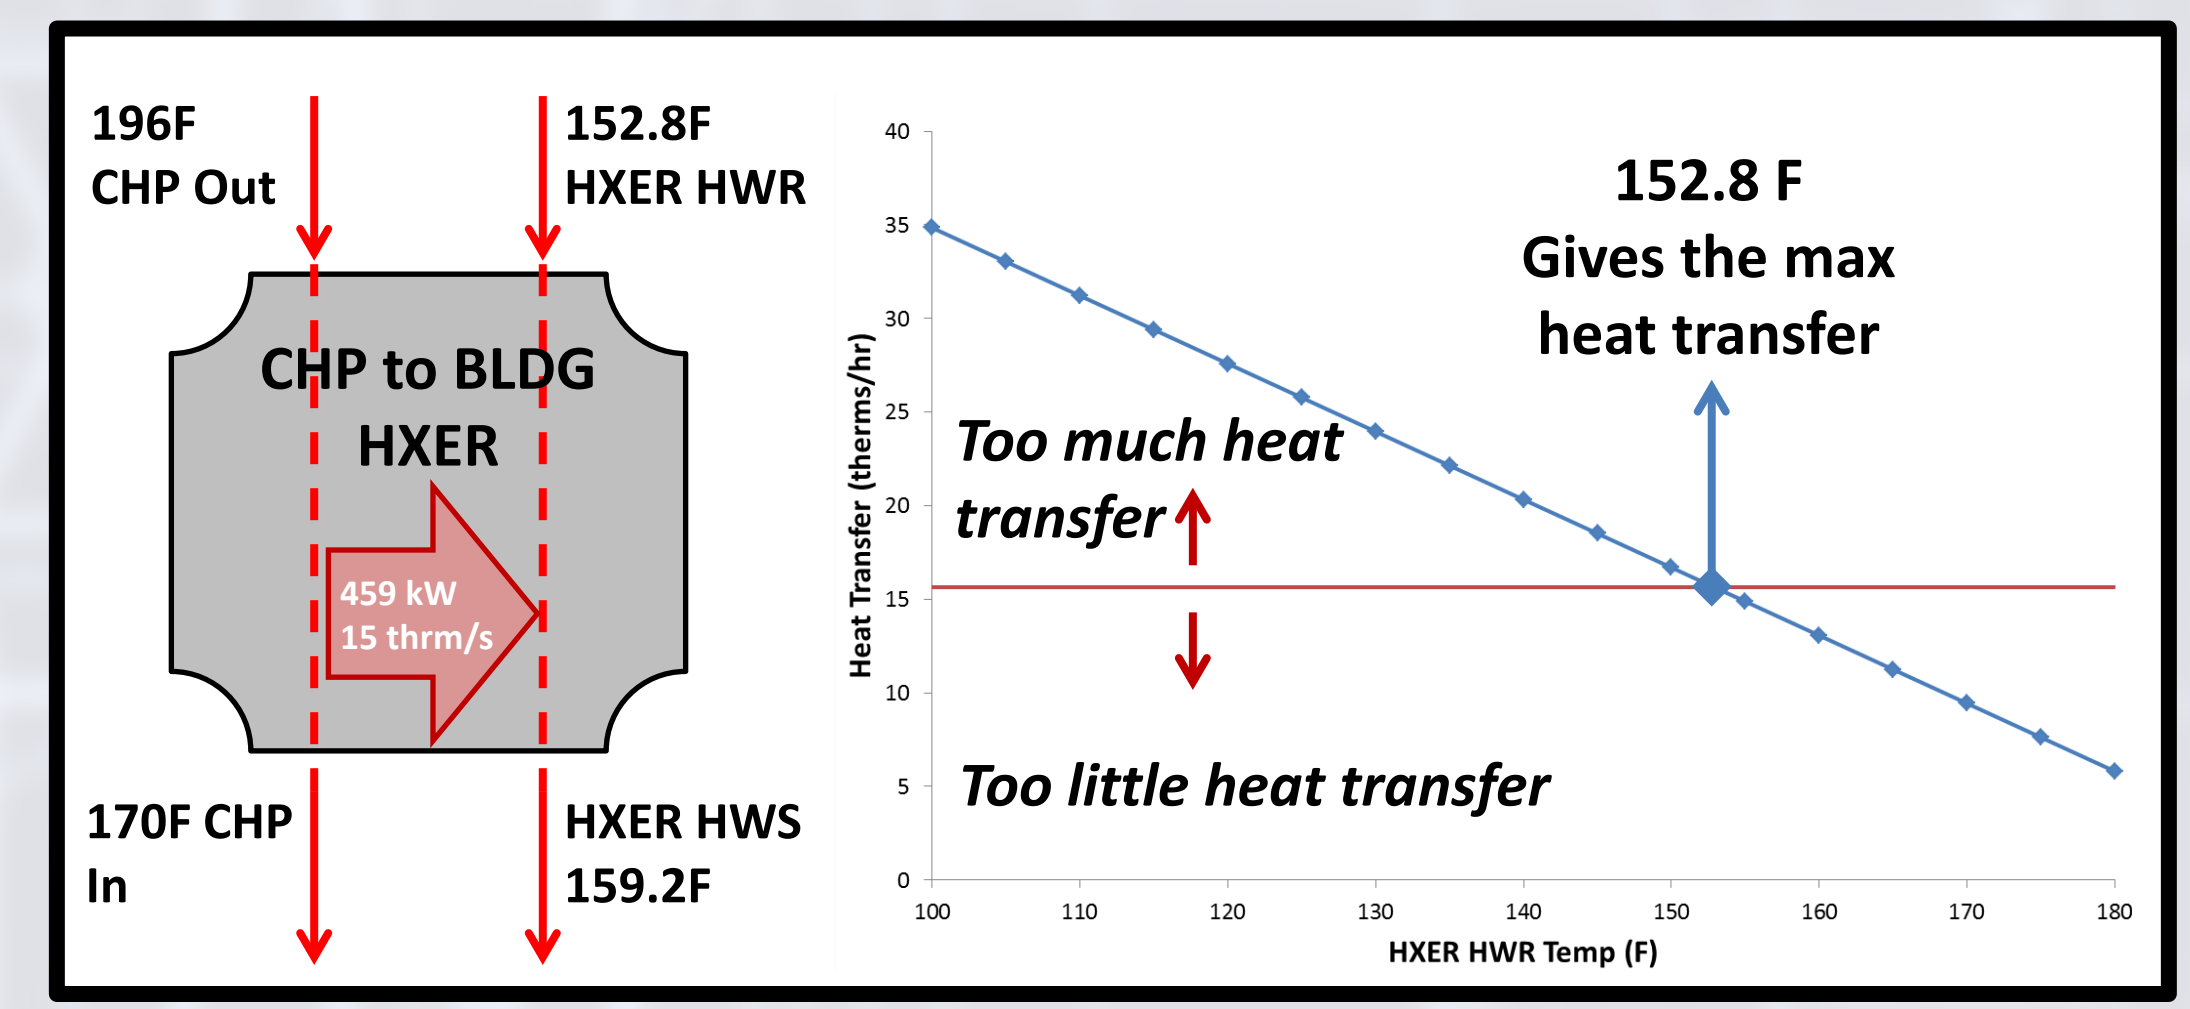

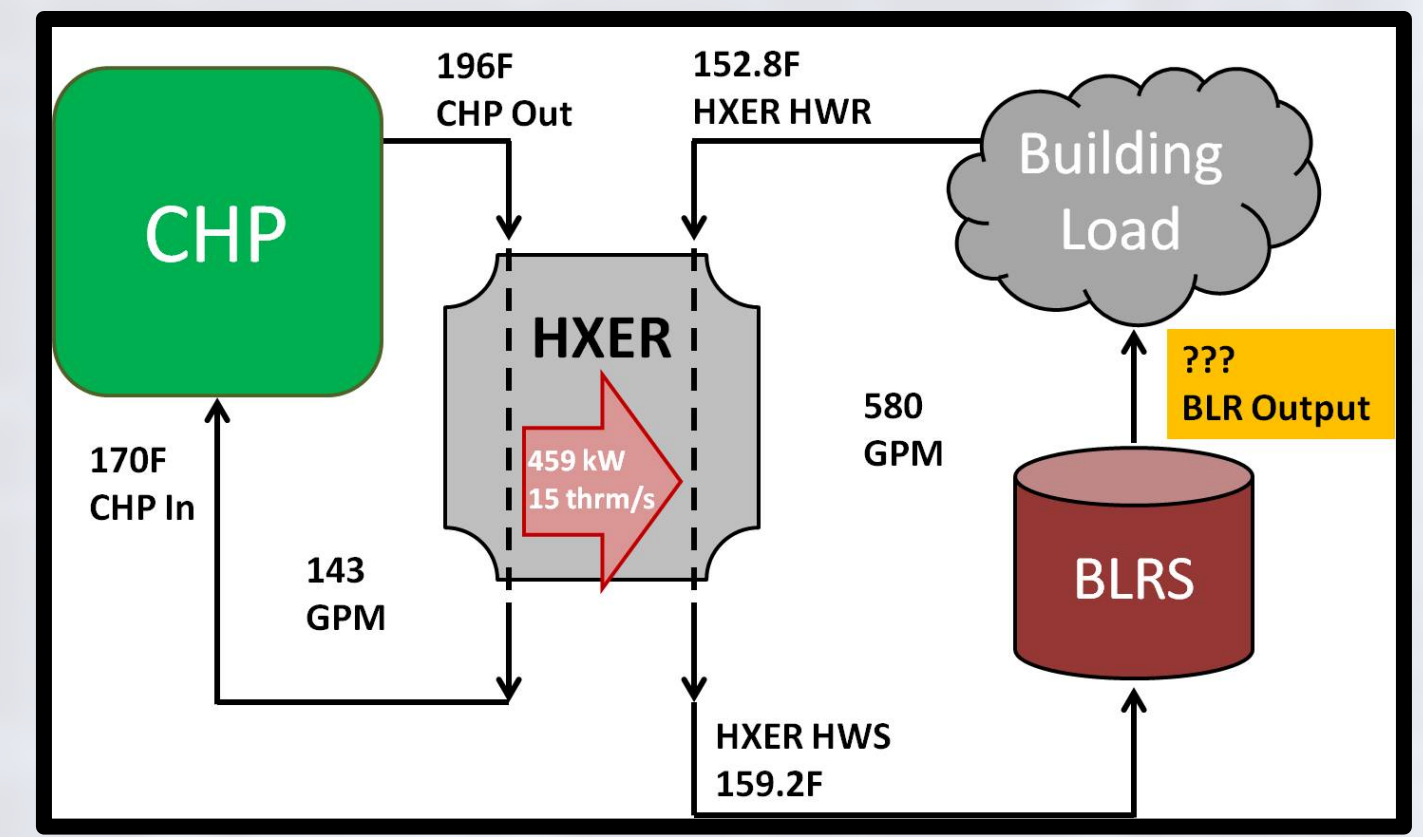

CHP Report – 41 CS 2015

- ❖ CHP saves money in electricity production only mode.
- ❖ CHP was not running for 31% of 2015.
- ❖ 53% of heat produced is dumped.

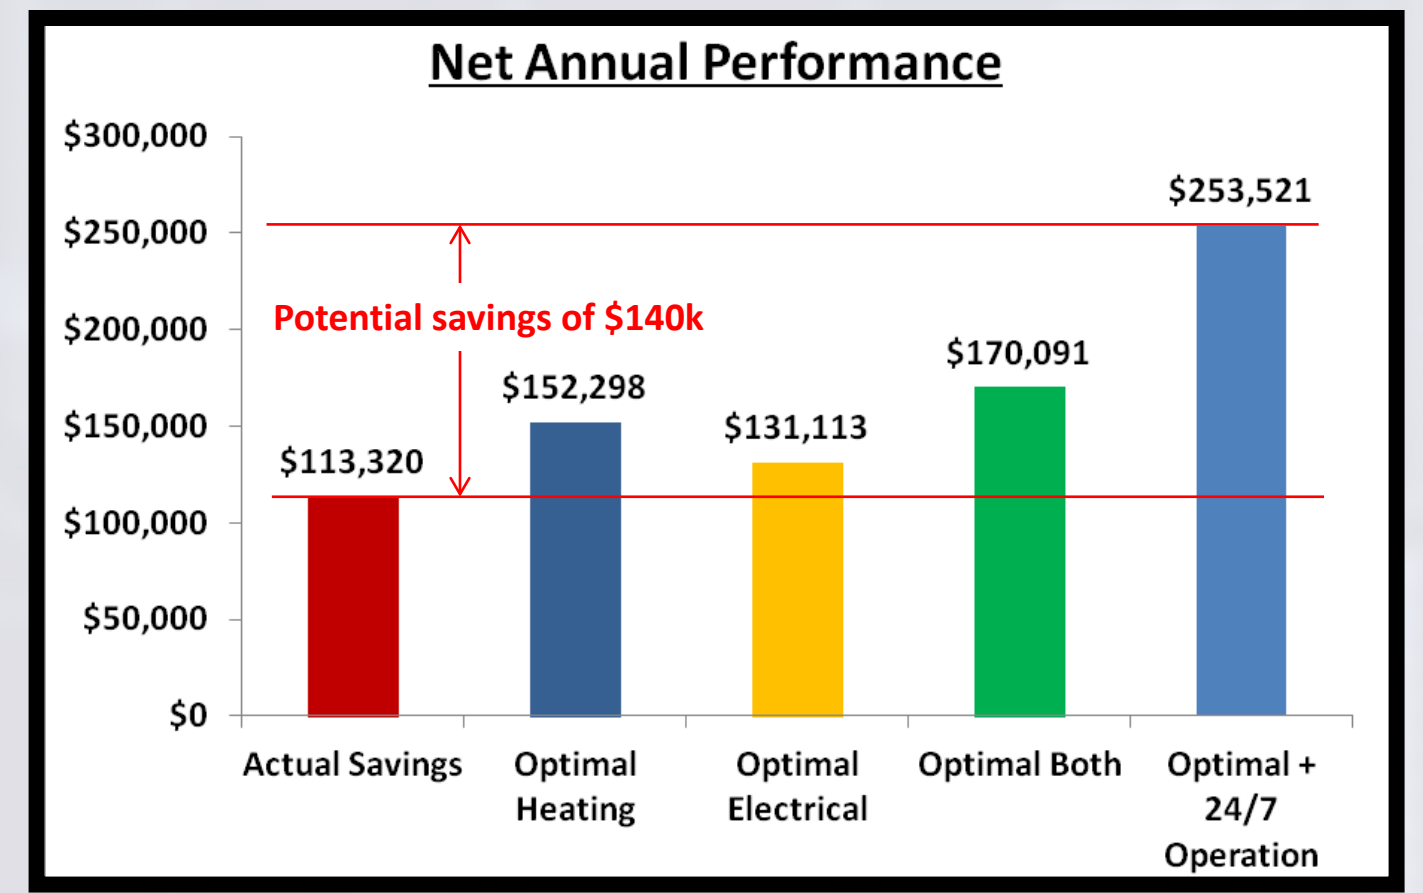

Heat Utilization Analysis (Future Work)

The CHP cannot deliver all of its heat if the building hot water is too hot. The building loop needs to be studied and the boiler load reduced.

Conclusions

- ❖ \$140k in potential annual savings identified*
- ❖ Increase uptime & modify hot water set-points to increase heat recovery
